Creating invariant test for exponential distribution

Kacper Kowalczyk

Testing problem

My goal is to develop a way of testing if set sample is from exponential distribution. Let $\mathcal{X} = (X_1, \dots, X_n)$ be iid sample.

$$H_0: \exists \lambda: X \sim EXP(\lambda)$$
 $H_1: \sim H_0$

Construcion of the test

Hypothesis H_0 is invariant under the group

$$G = \{g: g(X) = (aX_1, \dots, aX_n), a > 0\}$$

becouse if $X \sim Exp(\lambda)$ then $aX \sim Exp(\lambda/a)$.

Maximal invariant of this testing problem is

$$s(\mathcal{X}) = \left(\frac{X_1}{\bar{X}}, \dots, \frac{X_n}{\bar{X}}\right)$$

becouse if we assume $s(\mathcal{X}) = s(\mathcal{Y})$ then

$$\mathcal{Y} = (Y_1, \dots, Y_n) = \left(\frac{\bar{Y}}{\bar{X}}X_1, \dots, \frac{\bar{Y}}{\bar{X}}X_n\right) = g(\mathcal{X})$$

Test is invariant if our test statistic is a function of maximal invariant.

It is easy to see that, under the null, $Z = s(\mathcal{X})$ has approximately exponential distribution with parameter $\lambda = 1$. Thats, becouse maximum likelihood estimator of λ is $\hat{\lambda} = \bar{X}^{-1}$.

$$Z = \mathcal{X}/\bar{X} = \hat{\lambda}\mathcal{X} \sim Exp(\lambda/\hat{\lambda}) \approx Exp(1)$$

Furthermore $F(Z) \sim U(0,1)$. Then our we will define our test statistic as follows:

$$Q(\mathcal{X}) = \sup_{t \in \mathbb{R}} |\hat{F}_Z(t) - F_{Exp(1)}(t)| = \sup_{t \in (0,1)} |\hat{F}_{F_{Exp(1)}(Z)} - t|$$

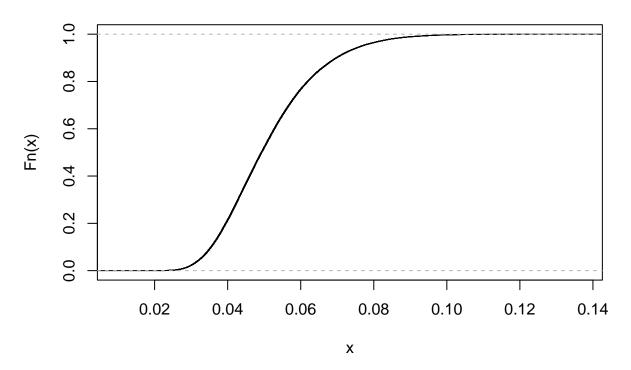

To find supremum it is sufficient to check only 2 * n points.

$$Q(\mathcal{X}) = \max_{i=1,...,n} \max \left\{ \left| \frac{i-1}{n} - F_{Exp(1)}(Z_{(i)}) \right|, \quad \left| \frac{i}{n} - F_{Exp(1)}(Z_{(i)}) \right| \right\}$$

As we can see this statistic is a function of our maximal invariant, therefore this test is invariant. To calculate p-value we will use Monte Carlo method.

```
MC <- 100000 # amount of Monte Carlo iterations needed to calculate
# empirical distribution of test statistics that is used to calculate p-values
                         #function that calculates test statistics
stat <- function(X){</pre>
  n <- length(X)
  Z \leftarrow X/mean(X)
  Z_ord <- sort(Z)</pre>
  s <- c()
  for(i in 1:n){
    one <- abs( i/n - pexp(Z_ord[i]) )</pre>
    two \leftarrow abs( (i-1)/n - pexp(Z_ord[i]) )
    s[i] <- max(one, two)
  return (max(s));
}
n <- 200 # sample size
TMC <- c() # list with values of test statistics under the null
for(i in 1:MC){
  X \leftarrow rexp(n)
  TMC[i] <- stat(X)</pre>
}
plot(ecdf(TMC))
```

ecdf(TMC)

Empirical power of the test

Power of the test is defined as probability of rejection the null. We will calculate the empirical power given samples from Gamma(a, 1) distribution with changing parameter $a = 0.05, 0, 1, \ldots, 3$. It is important to see that Gamma(1, 1) = Exp(1). One would hope for the power of the test when drawing from exponential distribution to be equal to significanse level.

```
Plot(a,POW, type = '1') #plot of empirical power
